ML Homework2

Due Date: 2019/03/28 (THU.) 23:59

TAs' email address: jhhlab.tw@gmail.com

Description:

1. Naive Bayes classifier

Create a Naive Bayes classifier for each handwritten digit that support **discrete** and **continuous** features.

- Input:
 - 1. Training image data from MNIST
 - You Must download the MNIST from this website and parse the data by yourself.
 (Please do not use the build in dataset or you'll not get 100.)
 - Please read the description in the link to understand the format.
 - Basically, each image is represented by $28 \times 28 \times 8$ bits (Whole binary file is in **big endian** format; you need to deal with it), you can use a char arrary to store an image.
 - There are some headers you need to deal with as well, please read the link for more details.
 - 2. Training lable data from MNIST.
 - 3. Testing image from MNIST
 - 4. Testing label from MNIST
 - 5. Toggle option
 - 0: discrete mode
 - 1: continuous mode

TRAINING SET IMAGE FILE (train-images-idx3-ubyte)

offset	type	value	description
0000	32 bit integer	0x00000803(2051)	magic number
0004	32 bit integer	60000	number of images
8000	32 bit integer	28	number of rows
0012	32 bit integer	28	number of columns
0016	unsigned byte	??	pixel
0017	unsigned byte	??	pixel
xxxx	unsigned byte	??	pixel

TRAINING SET LABEL FILE (train-labels-idx1-ubyte)

offset	type	value	description
0000	32 bit integer	0x00000801(2049)	magic number
0004	32 bit integer	60000	number of items
0008	unsigned byte	??	label
0009	unsigned byte	??	label
xxxx	unsigned byte	??	label

The labels values are from 0 to 9.

• Output:

- Print out the posterior (in log scale to avoid underflow) of the ten categories (0-9) for each image in INPUT 3. Don't forget to marginalize them so sum it up will equal to 1.
- For each test image, print out your prediction which is the category having the highest posterior, and tally the prediction by comparing with INPUT 4.
- Print out the imagination of numbers in your Bayes classifier
 - For each digit, print a 28×28 binary image which 0 represents a white pixel, and 1 represents a black pixel.
 - The pixel is 0 when Bayes classifier expect the pixel in this position should less then 128 in original image, otherwise is 1. (In other words, Bayes classifier expect to see a white pixel in this position if $\sum_{i=0}^{127} Pr(pixel=i) > \sum_{i=128}^{255} Pr(pixel=i)$. Otherwise, Bayes classifier expect to see a black pixel)

• Calculate and report the error rate in the end.

• Function:

- 1. In Discrete mode:
 - Tally the frequency of the values of each pixel into 32 bins. For example, The gray level of 0 to 7 should be classified to bin 0, gray level of 8 to 15 should be bin 1 ... etc. Then perform Naive Bayes classifier. **Note** that to avoid empty bin, you can use a peudocount (such as the minimum value in other bins) for instead.
- 2. In Continuous mode:
 - Use MLE to fit a Gaussian distribution for the value of each pixel. Perform Naive Bayes classifier.
- Sample input & output (for reference only)

```

2. Online learning

Use online learning to learn the beta distribution of the parameter p (chance to see 1) of the coin tossing trails in batch.

- Input:
 - 1. A file contains many lines of binary outcomes:

```
1 01010101110110110101
2 0110101
3 010110101101
```

- 2. parameter a for the initial beta prior
- 3. parameter b for the initial beta prior
- Output: Print out the Binomial likelihood (based on MLE, of course), Beta prior and posterior probability (parameters only) for each line.
- Function: Use Beta-Binomial conjugation to perform online learning.
- Sample input & output (for reference only)
 - Input: A file (here shows the content of the file)

```
$ cat testfile.txt
   0101010101001011010101
   0110101
